

Why?

Let's say you want to show that the language  $\text{ALL}_{\text{CFG}}$  is undecidable.

$\text{ALL}_{\text{CFG}} = \{ \langle G \rangle \mid G \text{ is a CFG and } L(G) = \Sigma^* \}$

$A_{\text{TM}} \leq \text{ALL}_{\text{CFG}}$

We are going to look at theories that would allow us to do reductions such as  $A_{\text{TM}} \leq \text{ALL}_{\text{CFG}}$ .

## Definition

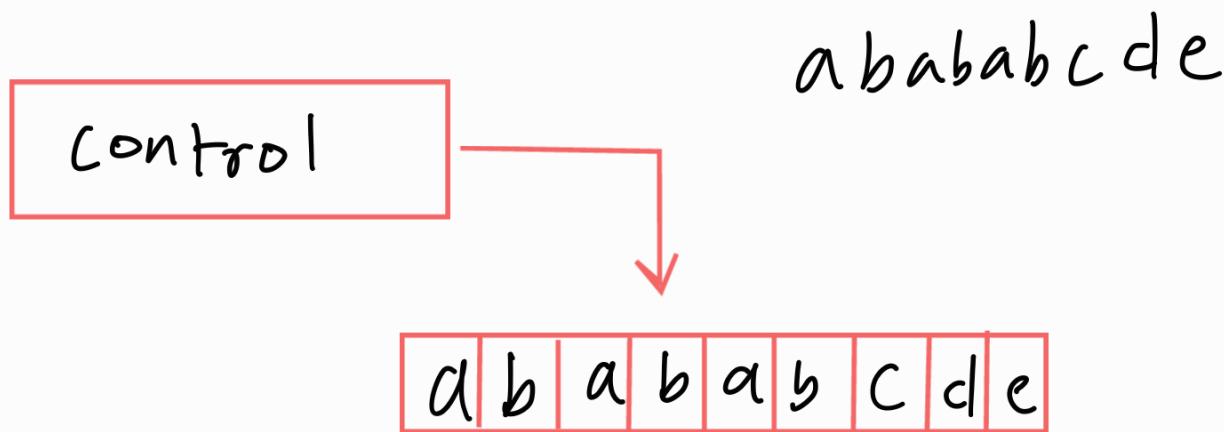

Let  $M$  be a Turing Machine and  $w$  an input string. An accepting computation history for  $M$  on  $w$  is a sequence of configurations  $c_1, c_2, \dots, c_e$  where  $c_1$  is the start configuration of  $M$  on  $w$ ,  $c_e$  is the accepting configuration of  $M$  on  $w$ , and each  $c_i$  legally follows from  $c_{i-1}$  according to rules of  $M$ .

A rejecting configuration is defined similarly, except  $c_e$  is the rejection configuration.

- \* Computation histories are finite sequences.
- \* If  $M$  does not halt on  $w$ , then there are no accepting or rejecting computation history

# Linear Bounded Automaton (LBA)

This is a restricted type of TM wherein the tapehead isn't permitted to move off the portion of the tape containing the input. If the machine tries to move its head off either end of the input, the head stays where it is.

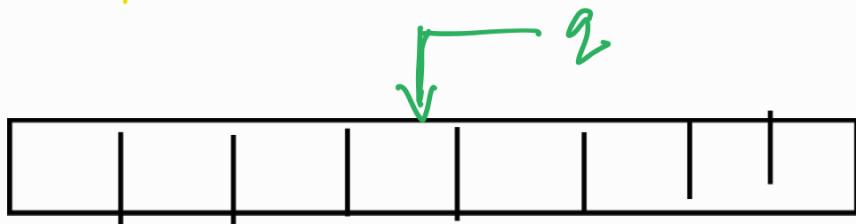

Now we define the following language

$$A_{LBA} = \{ \langle M, w \rangle \mid M \text{ is a LBA and } M \text{ accepts } w \}$$

Theorem 5.9  $A_{LBA}$  is decidable.

Lemma 5.8 : Let  $M$  be a LBA with  $q$  states and  $g$  symbols in the tape alphabet. There are exactly  $q^n g^n$  distinct configurations of  $M$  on a tape of length  $n$ .

$$g \times g \times g \times g \times \dots \times = g^n$$

$$q^n g^n$$

$g$  - Size of the tape alphabet

$n$  - Size of the input

$q$  - # of states in the LBA.

$A_{LBA}$  is decidable proof:

I am going to create a decider for  $A_{LBA}$  where the input is  $\langle M, w \rangle$   $M$  is a LBA,  $w$  is a string.

I am going to create TM  $L$  that decides  $A_{LBA}$ .

$L =$  on input  $\langle M, w \rangle$

1. Simulate  $M$  on  $w$  for  $qn^q^n$  steps or until it halts.

2. If it halts on an accept state, accept

3. If it halts on a reject state, reject

4. If  $M$  does not halt during

$q^{ng^n}$  steps , reject.

// M exhaust all configs

// There is a loop

Theorem 5.10  $E_{LBA}$  is undecidable.

$$A_{TM} \leq E_{LBA}$$

$$E_{LBA} = \{ \langle M_1 \rangle \mid M \text{ is a LBA and } L(M) = \emptyset \}$$

Idea: I am going to create a LBA  $B$  such that the language of  $B$  recognizes all accepting computation histories for  $M$  on  $w$ . If  $M$  accepts  $w$ ,  $L(B)$  contains exactly one string that is the computation history for  $M$  on  $w$ . If  $M$  does not accept  $w$ ,  $L(B) = \emptyset$ .

We construct LBA  $B$  as follows:  
( $M$  and  $w$  are encoded inside this)

$B = \text{on input } \langle x \rangle$

1. If  $x$  is an accepting computation history for  $M$  on  $w$ ,  
then accept  $x$ .

\*  $B$  looks at following 3 conditions,

1.  $C_1$  is the starting config for  $M$  on  $w$ .
2. Each  $C_{i+1}$  legally follows  $C_i$
3.  $C_\ell$  is the accepting config for  $M$  on  $w$ .

$\# C_1 \# C_2 \# C_3 \# \dots \# C_\ell \#$

Assume  $R$  is the decider for  $E_{LBA}$ .

We construct TM  $S$  for  $A_{TM}$

$S = \text{on } \langle M, w \rangle$ , where  $M$  is a TM  
and  $w$  is a string

1. Construct LBA  $B$  with  $\langle M, w \rangle$  encoded inside it
2. Run  $R$  on  $\langle B \rangle$
3. If  $R$  accepts ; reject
4. If  $R$  rejects ; accept

$\therefore E_{LBA}$  is undecidable

$$\text{ALL}_{\text{CFG}} = \{ \langle G \rangle \mid G \text{ is a CFG and } L(G) = \Sigma^* \}$$

Proof is similar to theorem 5.10 but with a slight twist.

$$A_{\text{TM}} \leq \text{ALL}_{\text{CFG}}$$

Proof Idea: I am going to create a CFG  $G$  for a given  $\langle M, w \rangle$  where  $L(G) = \Sigma^*$  if and only if  $M$  does not accept  $w$ .

If  $M$  accepts  $w$ , we make sure that the computation history for  $M$  on  $w$  is not generated by the  $G$ .

To make my life easier we are going to create a PDA  $D$  that behaves as above.

- Let the computation history for  $M$  on  $w$  be

$$\# c_1 \# c_2 \# c_3 \# \dots \# c_l \#$$

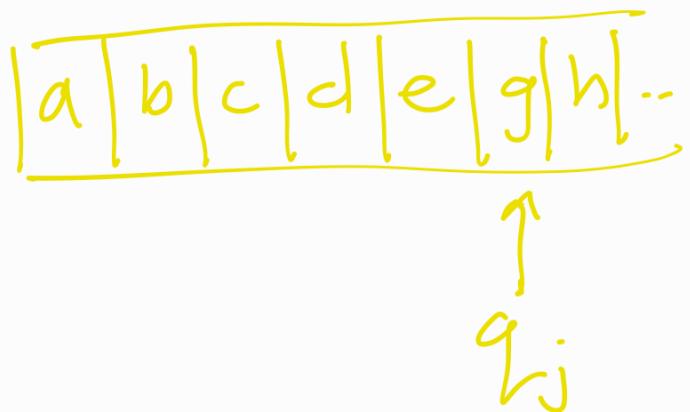

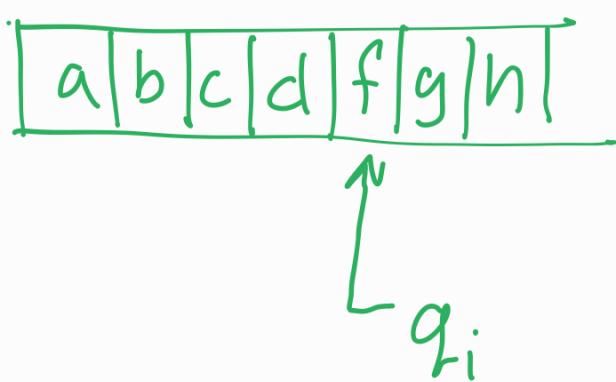

-  $D$  accepts all strings

1. do not start with  $c_1^*$  branch
2. do not end with  $c_l^*$  branch
3. Some  $c_i$  does not yield  $c_{i+1}$

- Scan the input until it non-deterministically decides that it has reached  $c_i$ . It pushes  $c_i$  on the stack until we reach  $\#$ . Then  $D$  pops the stack to compare  $c_{i+1}$ .

They should match all except the head position.

$$abcdq_i fgh \Rightarrow abcdeq_j gh$$

$$f(q_i, f) = (q_j, e, R)$$

Proof: Assume  $R$  is the decider for  $\text{ALL}_{\text{CFG}}$ . Construct TM  $S$  that decides  $A_{\text{TM}}$ .

$S$  = "on input  $\langle M, w \rangle$  where  $M$  is a TM and  $w$  is a string

1. construct PDA  $D$  with  $\langle M, w \rangle$  encoded inside.
2. convert  $D$  into CFG  $G$ .

3. Run  $R$  on  $\langle G \rangle$

4. If  $R$  accepts, reject

If  $R$  rejects, accept

$S$  is a decider for  $A_{TM}$ .

But  $A_{TM}$  is undecidable.

This is a contradiction.

$\therefore$   $ALL_{CFG}$  is undecidable.
